

What NDACC ozone lidars are telling us about long term satellite measurements

5. Godin-Beekmann, P.J. Nair, NDACC lidar and satellite measurement teams

Lidar ozone measurements

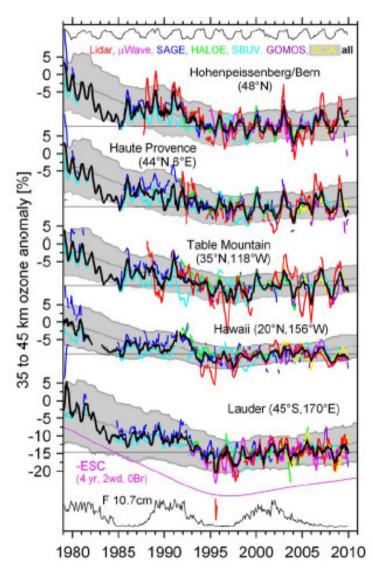

DIAL Method: DIfferential Absorption Lidar

- Emission of 2 laser beams in the UV range $(\lambda_{on,}, \lambda_{off})$ with different ozone absorption cross-section
- Self calibrated measurements
- Units: ozone nb density vs altitude
- Sensitive to volcanic aerosols: detection of N₂ Raman wavelengths
- Altitude range: 10-50 km, varying altitude resolution (0.3 5 km) profiles noisier above ~40 km
- temporal resolution; 1- 4 hours depending on laser power and rep. rate
- Night-time only and clear skies

Evolution of ozone in the upper stratosphere

Ozone recovery?

- Steinbrecht et al., 2006,
 Steinbrecht et al., 2009.
- Ozone anomalies in the range
 35 45 km
- Observed data: 5 month running mean
- Satellite: zonal average
- Grey area: CCMval simulation,
 24 month running mean ± 2 σ

Comparision of ozone profile time series at OHP

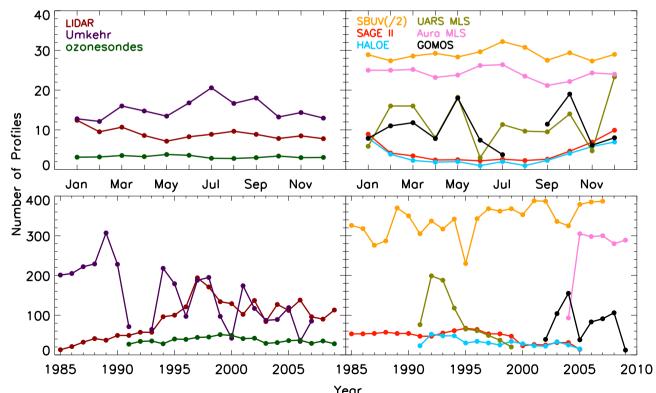

- Ground-based: lidar, Umkehr, ozone sondes
- Satellite: SAGE II, SBUV(/2), HALOE, MLS (UARS & Aura), GOMOS

Heterogeneous data sampling

 $\pm 2.5^{\circ}$ or 5° lat

 \pm 5° or 10° long

Nair et al., ACPD, 2010

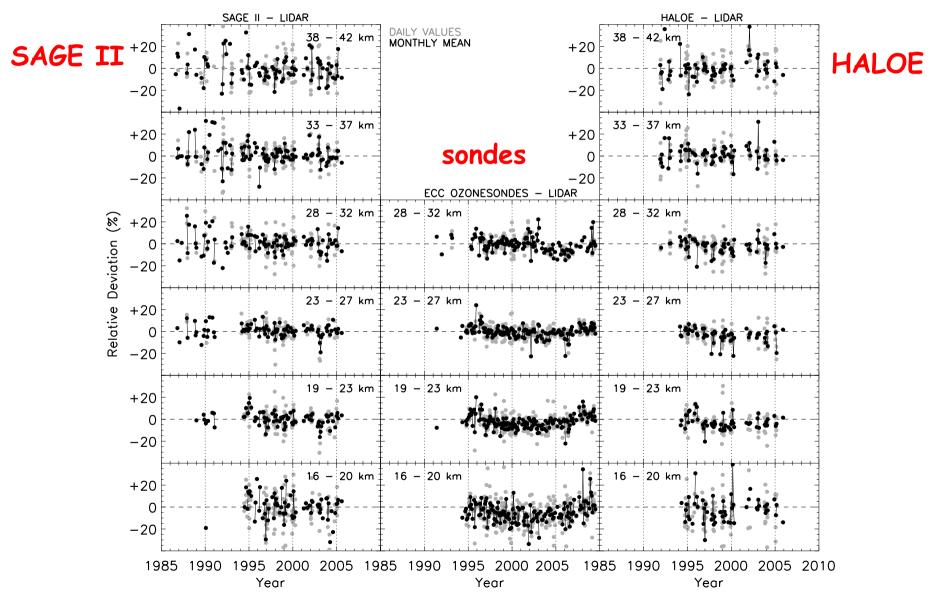

Data Conversion: Averaging Kernel issue

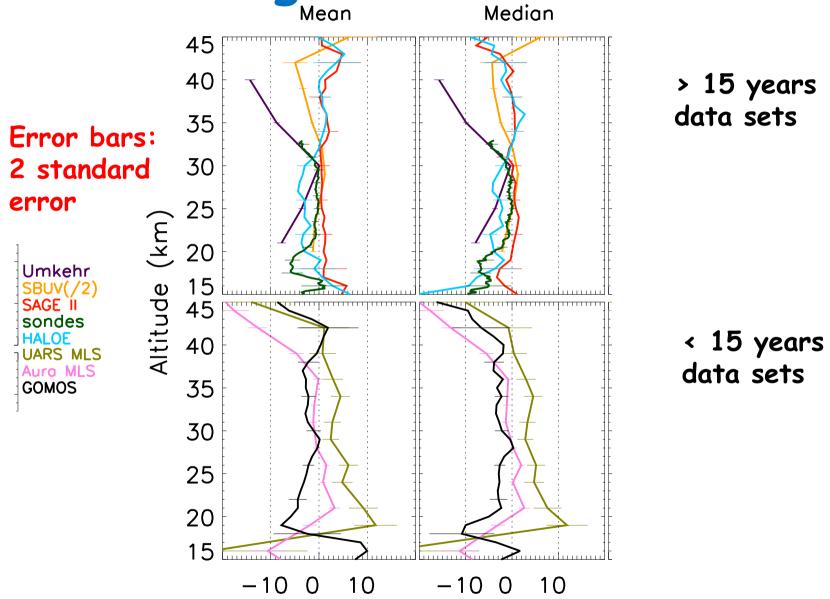

SBUV(/2), lidar and the lidar profile convolved using SBUV/2 averaging kernels (left) SBUV/2 averaging kernels (middle) and the average relative difference (right panel) at OHP.

Example of coincident data series

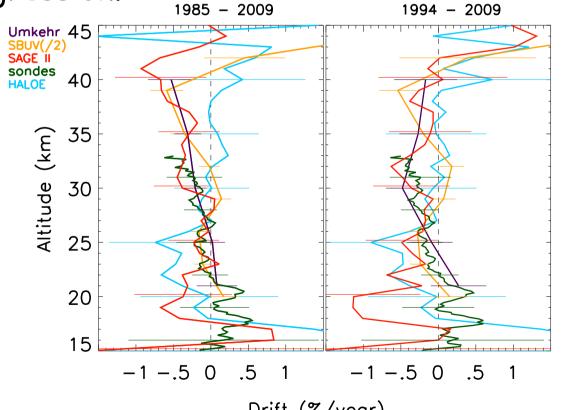

Average biases at OHP

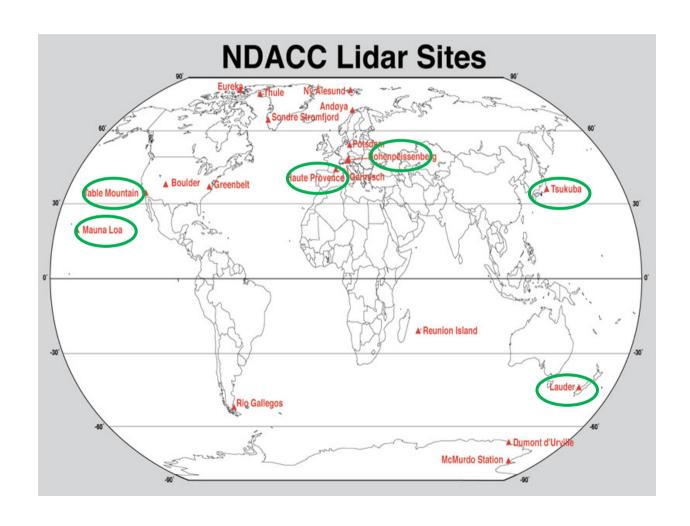

Drifts of ozone time series as compared to the OHP lidar

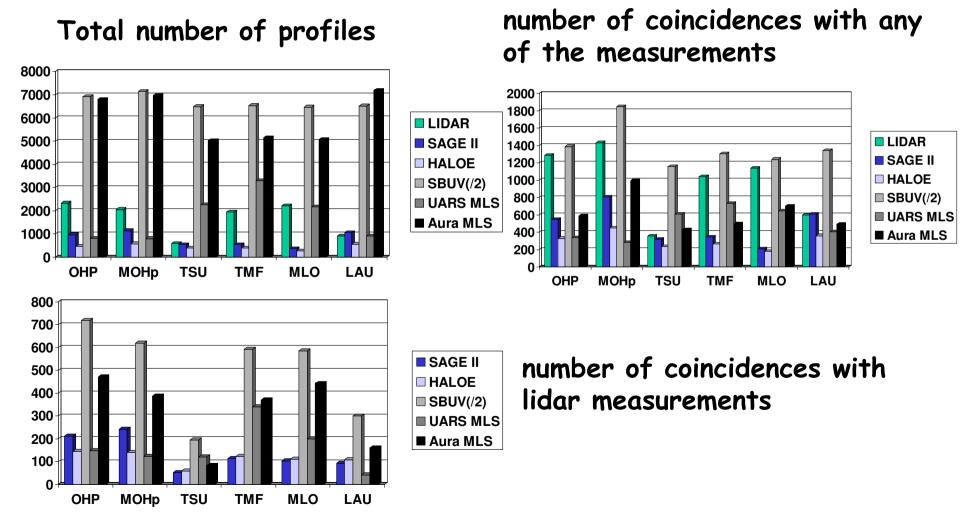

The drifts are derived from the time series of monthly averages of the relative differences of ozone using simple linear regression.

Study at 6 NDACC lidar stations

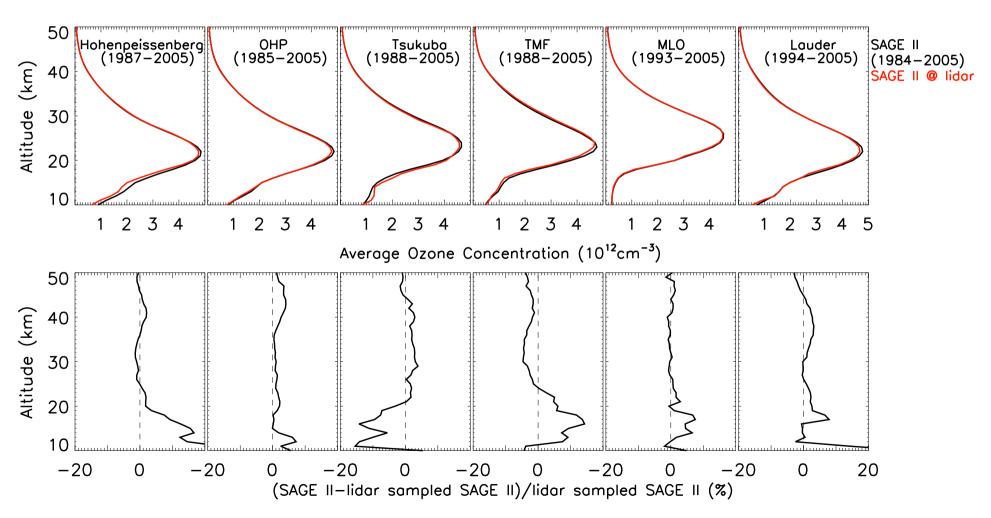

Data sampling

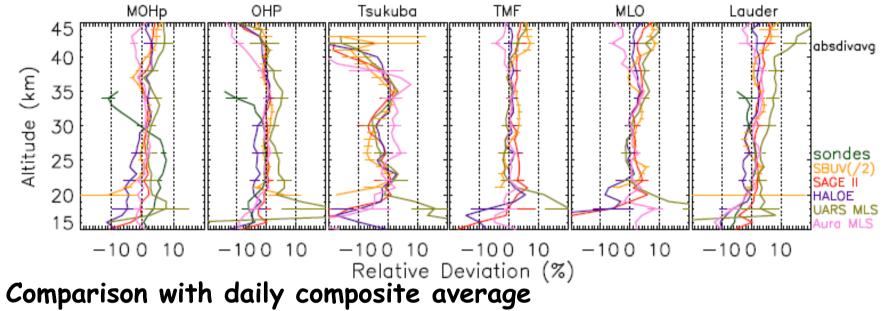

Clear sky bias

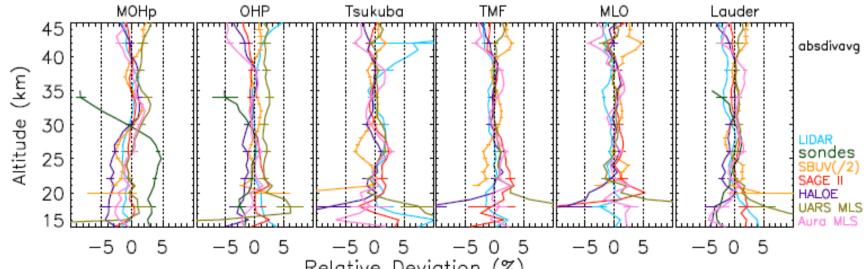

Average ozone concentration of SAGE II ozone profiles for the non-coincident and coincident days with lidar and relative deviation

Average differences

Comparison with lidar measurements

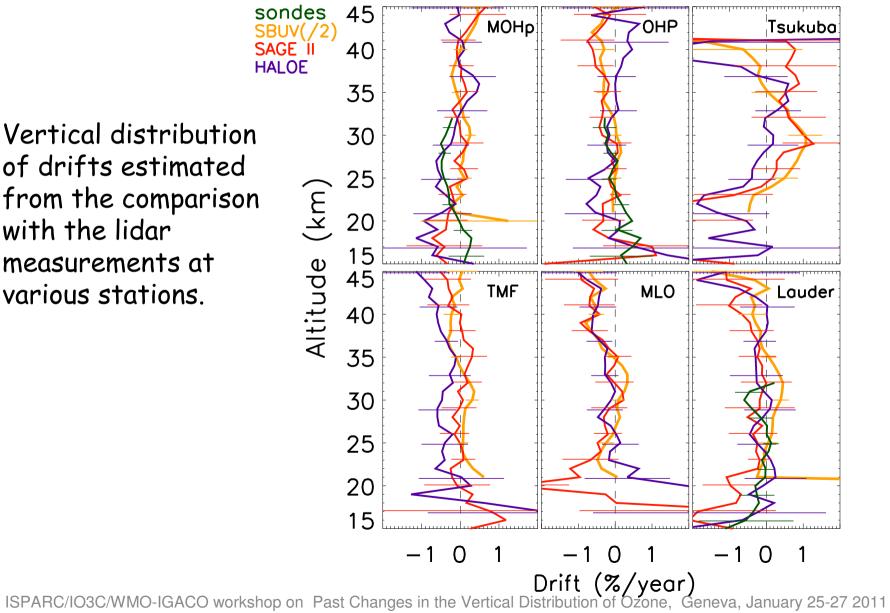

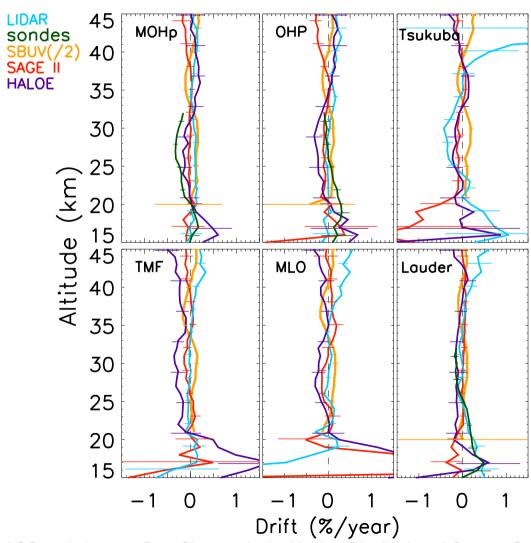

Relative Deviation (%)
ISPARC/IO3C/WMO-IGACO workshop on Past Changes in the Vertical Distribution of Ozone, Geneva, January 25-27 2011

Drift with lidar measurements

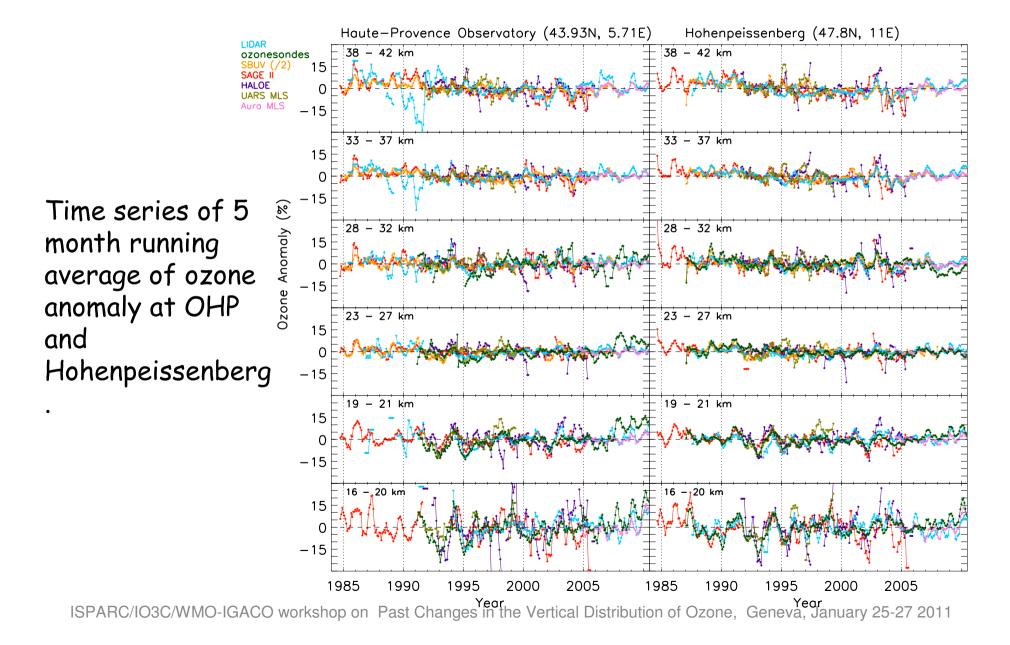

Vertical distribution of drifts estimated from the comparison with the lidar measurements at various stations.

Drift with all measurements daily average

Deasonalised time series

Deasonalised time series (2)

Tsukuba (36N, 140E)

38 - 42 km

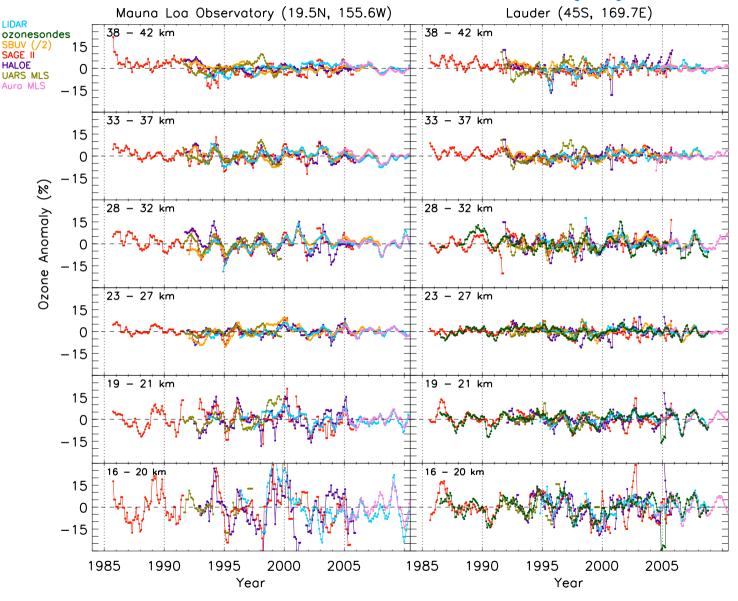

Table Mountain facility (34.5N, 117.7W)

Deasonalised time series (3)

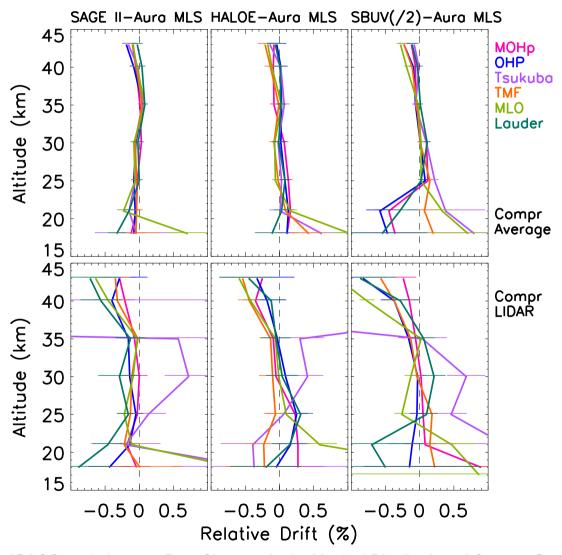

Time series of 5 month running average of ozone anomaly at Mauna Loa Observatory and Lauder.

Long term relative differences

Drift of long term composite time series

Conclusions

- 5 NDACC stations provide lidar ozone profile time series since 1991 or before
- Average differences within ± 5 % at 20-45 km
- Drifts: below ± 1 %/year at 20-45 km
- Smaller average and drifts using daily composite averages
- Comparison of monthly averages also possible
- Issues with continuation of the time series (Tsukuba, Lauder)
- 2010-2011: ISSI team on O3 and T lidar algorithms
